

Early Journal Content on JSTOR, Free to Anyone in the World

This article is one of nearly 500,000 scholarly works digitized and made freely available to everyone in the world by JSTOR.

Known as the Early Journal Content, this set of works include research articles, news, letters, and other writings published in more than 200 of the oldest leading academic journals. The works date from the mid-seventeenth to the early twentieth centuries.

We encourage people to read and share the Early Journal Content openly and to tell others that this resource exists. People may post this content online or redistribute in any way for non-commercial purposes.

JSTOR is a digital library of academic journals, books, and primary source objects. JSTOR helps people discover, use, and build upon a wide range of content through a powerful research and teaching platform, and preserves this content for future generations. JSTOR is part of ITHAKA, a not-for-profit organization that also includes Ithaka S+R and Portico. For more information about JSTOR, please contact support@jstor.org.

The withdrawal from the custom houses of serum from abroad, ordered by private persons, is permitted by the commission on condition that in each case a statement of the place of manufacture shall accompany the consignment, and that only serums from institutions, the names of which shall be furnished to the customs officers by the president of the commission, shall be admitted.

THE PREVENTION OF THE SPREAD OF SCARLET FEVER.

[Prepared under the direction of the surgeon-general by P. A. Surg. H. D. Geddings, Acting Director Hygienic Laboratory.]

In view of the receipt by the Bureau of inquiries from various sources as to measures looking to the prevention of the spread of scarlet fever, and methods of disinfection to be followed upon the termination of cases of the disease, there is reproduced here a publication which appeared in the PUBLIC HEALTH REPORTS of December 13, 1901, by P. A. Surg. H. D. Geddings, U. S. Marine-Hospital Service, upon methods of disinfection to be pursued against scarlet fever, to which is appended a circular letter by Acting Asst. Surg. J. Y. Porter, State health officer of Florida, to local health officers and the medical profession in his State—the one article naturally supplementing the other.

Disinfection against scarlet fever.

[By H. D. GEDDINGS, Passed Assistant Surgeon, U. S. M. H. S.]

In the consideration of this subject, as in all other subjects connected with disinfection, the two general factors must be considered of the nature of the infection and the best means for destroying it.

As is well known, infection or communicability may be of two general varieties—the immediate, in which the disease is communicated by actual contact, and the mediate, in which the infection is communicated to articles or things and thence transmitted to others.

The infection of scarlet fever is of both natures. Immediate infection certainly can occur by the contact of a susceptible person with one suffering with the disease, but still more probable is it that the infection is highly mediate in its character and is communicated to the surroundings of the patient, furniture of rooms, bedding, clothing, etc., largely through the fine, scaly particles, which are given off by the patient and diffused with the dust of the room. This desquamation constitutes the essentially dangerous feature of scarlet fever from the point of view of the health officer, for even after his desquamatory process has been apparently completed it may be renewed and the patient again become capable of conveying infection. The poison clings with great persistency to clothing of all kinds and the furniture of a room, specially that which is upholstered. It is exceedingly tenacious in its character, and clothing which has been put away for months, or even for years, may, unless thoroughly disinfected, again convey contagion.

Observations which have been made from time to time show that the disease has been often transmitted through the medium of the milk supply, and recent experience in Detroit, Mich., has shown that even when the milk supply was not at fault the disease has been communicated through the medium of milk tickets which were repeatedly used.

The specific germ of the disease is not known. Therefore, disinfection

tion of rooms or apartments where the disease has prevailed must be conducted on general principles. These disinfecting processes differ in no wise from those employed for the other acute infectious or communicable diseases. The poison, while very enduring, is probably of a not very resistant nature, which is fortunate in view of the high contagiousness of the disease and its serious nature when prevalent in epidemic form.

It is desired to dwell with particular emphasis upon the danger which accompanies the desquamatory stage of the disease, which makes it different from the other acute infectious diseases. The effort must be not only to destroy the contagion conveyed in these particles, but to prevent the scattering of the said particles into the apartment where they become mingled with the dust always present in the atmosphere. Therefore, each case of scarlet fever must be a study in itself. No hard and fast rule can be laid down as to the period of time after the appearance of the disease when disinfection should be practiced. So long as the desquamation of the patient continues so long is he or she liable to reinfect a room or apartment which has already been disinfected, no matter how thorough that disinfection has been. Observation alone can determine this point, and until the desquamation has ceased or means have been taken to minimize its danger, it is useless to undertake the disinfection of the sick room.

Much may be accomplished in the matter of prevention of spread of the disease by the thorough bathing of the patient with antiseptic baths, followed by inunction with any of the animal or vegetable oils, or with a vaseline which has been rendered mildly antiseptic, with carbolic acid, boracic acid, etc.

Methods of disinfection.

As before remarked, all methods are applicable, and if faithfully and intelligently applied all are probably efficacious. Obviously there must be a difference in the methods, depending upon the nature of the articles or materials to be disinfected. For the mattress of the sick room a surface disinfection may be accomplished, either by formaldehyd gas, by sulphur dioxide, or, if the infection is supposed to be deep seated, which it possibly may be, steam or immersion in hot water may be required.

Steam should only be applied in apparatus specially designed to obtain efficient action, and if immersion in hot water is the method determined upon, care must be exercised that the article to be disinfected is totally submerged, that the water is at the actual boiling point, and that the boiling continue for twenty minutes or half an hour.

Particular attention should be taken to effectually sterilize the dust of the living room, and the walls, ceiling, and floor of the apartment. Carpets, if any, should be removed and treated either by steam, by immersion in hot water, or by thorough exposure to one of the gaseous disinfectants to be considered hereafter. The walls, ceiling, and floor had better be thoroughly wiped down with a solution of bichloride of mercury, 1-1000 in strength, or carbolic acid of a strength of 5 per cent. This cleaning must be thorough, as any dereliction will almost certainly meet its punishment in a renewal of the infection.

Disinfection with sulphur dioxide would be perfectly efficient against scarlet fever, but is open to the objection that, when applied in the proper germicidal strength for a sufficient length of time, it will injure or ruin any clothing, hangings, upholstery, and furniture which may be

subjected to its action. Undoubtedly it will sometimes become necessary to use this agent, in which case, with the limitation as to usefulness mentioned above, $3\frac{1}{2}$ to 4 pounds of powdered sulphur should be burned in the tightly closed room to every 1,000 feet of space, all cracks, windows, and doors being tightly sealed, and the room should be kept closed from twelve to twenty-four hours. Due care should be taken that the vessels in which the sulphur is burned should be immersed in other vessels containing water, which, by its vaporization, renders the sulphur dioxide germicidally active, and without which moisture the process is useless.

Probably formaldehyd is the best germicide for the disinfection of the sick room or for the bedding and fabrics therein contained, with the possible exception of mattresses. Four methods of using the formaldehyd gas may be mentioned, namely:

First. The sheet method;

Second. The Kuhn lamp;

Third. By evolving formaldehyd from its watery solution by apparatus without pressure, and

Fourth. By the autoclave.

First. The sheet method may be briefly described as spraying suspended sheets with 5 ounces of the 40 per cent solution of formaldehyd gas (formalin) for each 1,000 cubic feet of space; the time of exposure to be not less than five hours. The quantity should be divided between several sheets, and the liquid should be sprayed upon these sheets so as to form small drops rather than to effect a general wetting of the surface.

Second. The Kuhn lamp depends for effectiveness upon the production of formaldehyd by oxidation of wood alcohol by passing it over a platinized surface in a state of incandescence. The method requires the use of about 20 ounces of wood alcohol to about each 1,000 cubic feet of space, and the time of exposure should be not less than six hours, counting from the time when the alcohol is all volatilized. One objection that has been made is that it may require a large number of lamps or generators. This may be avoided by placing the generator immediately within the door of the apartment undergoing disinfection upon a board or other suitable contrivance. The apparatus may be withdrawn after the completion of the volatilization of the alcohol (about an hour and a half) by quickly opening the door and withdrawing it by means of a cord or rope previously attached to it. This can be quickly done without loss of gas, and the apparatus is then available for use in another apartment.

Third. The third method involves the employment of various forms of formaldehyd regenerating apparatus, of which the Trenner-Lee, the Lentz, and others too numerous to mention, may be accepted as types.

The process depends upon the principle of evolving without pressure formaldehyd gas from its watery solution, to which 1 per cent of glycerin has been added. The process is one, so to speak, of disinfection by distillation. The apparatus is in sight and the gas is injected into the room or apartment through the keyhole by means of a flexible tube. Twenty ounces of the formaldehyd solution, with the addition of 1 per cent of glycerin should be used for each 1,000 cubic feet of space, and the apartment kept closed for six hours.

Fourth. Disinfection by the autoclaves manufactured by the Kny-Scherer Company and the Kensington Engine Works, differs from the above process in that the formaldehyd gas is generated by heating formalin mixed with a neutral salt in a retort under a pressure of at least

45 pounds to the square inch. At least 10 ounces of fluid should be used for each 1,000 cubic feet of space, and the time of exposure may be varied from two to twenty-four hours; six hours in general practice would be amply sufficient, but care must be taken that to the formaldehyd solution is added 20 per cent of a neutral salt, such as borax or calcium chloride, and that the pressure in the apparatus is from 45 to 60 pounds per square inch. The gas is injected into the room through the keyhole by means of the nozzle and flexible rubber tube.

Any of the methods above given will prove thoroughly efficient in practice. Thoroughness of work is in this, as in all other disinfecting processes, an essential requirement; nothing must be neglected—nothing left to chance.

The infection of scarlet fever is very insidious, very long lived, and only fairly resistant. It must be thoroughly reached in order to be destroyed; but it is believed that the application of any one of the methods given above, or any combination of the methods, will result in thorough destruction of the infection if care is exercised in discriminating as to the time when the disinfecting process is employed. This should not be before the desquamation of the patient is complete, and even after the desquamatory process is apparently completed, care should be exercised as to frequent bathing of the patient, and the application of the oily or greasy substances made mention of above.

In this, as in all other processes connected with disinfection or protection against infectious and contagious diseases, almost as much will depend upon the judgment of the health officer or attending physician as upon the method.

Circular letter on scarlet fever.

[By JOSEPH Y. PORTER, State health officer of Florida.]

JACKSONVILLE, FLA., ———, 190—.

SIR: Scarlet fever is reported from your city, and some of your citizens express great apprehension that your physicians are not adopting sufficiently restrictive measures to prevent a general spread of the disease. It occurs, therefore, to the State board of health to indicate to you in a friendly manner, and without any intention to officiously intrude upon the prerogatives of your city health government, certain features of management which it is thought may aid your health authorities in their methods of eradication of scarlet fever from your community, and which, although very probably well known, may have been lost sight of or overlooked.

A few general principles apply to communicable diseases which, unrestrained, tend to become epidemic in character.

First. Cases should be isolated, not partially but completely, from well members of the family, and in order to do this effectively, a room for the treatment of the case or cases should be selected in the dwelling or home, well ventilated, and as far removed from the other occupants as is possible. To avoid a great deal of trouble after the termination of the case, and to lessen the danger of retained infection, the room should be as scantily furnished as will be conducive to comfort and hygienic care of the patient. Carpets, rugs, curtains, and superfluous articles of furniture should be removed, the floors, ceilings, and window

casings wiped off to remove dirt and dust, and ample receptacles provided for disinfecting solutions, before the sick one is moved in.

Second. Only those who intend to nurse the sick and remain with the case should be allowed in the sick room. On no conditions should the nurses be permitted to have communication with the well members of the family or with the outside public without completely changing outer garments and disinfecting face, hands, hair, and beard. As this process is a troublesome thing to do several times a day, it is the better plan for nurses in contagious diseases to keep themselves isolated with their patients.

Third. During the progress of contagious sickness, articles used in the sick room should be disinfected before leaving the apartment. Tumblers, mugs, dishes, knives, and forks after being used by the sick should be dipped in a disinfecting solution or immersed in actually boiling water for fifteen minutes, and body linen, bedclothes, towels, handkerchiefs, and, in fact, every textile article used in or about a sick room or person, should be immersed for several hours in a strong germicidal solution before being removed from the room to be laundered. Disinfection of excreta of the sick—stools, urine, and discharges of every kind—should always be disinfected before being taken in covered vessels from the sick room. In some diseases, such as diphtheria and scarlet fever, where there is apt to be much mucous and membranous discharge from the mouth and nostrils, the use of paper napkins is preferable, for these can be burned in a fireplace or stove in the room. This is also a good method of disposal of such soiled textile articles which have no particular value.

Fourth. On the termination of a case of contagious sickness, by complete recovery of the patient or by death, the apartment should be disinfected before being again used. Mattresses, pillows, and such bedroom furnishings that can not be boiled should be burned after removal from the room in covered boxes or vessels with impervious coverings.

The foregoing are some of the precepts which should be followed when dealing with any of the infectious and contagious diseases, and are equally applicable to cases of diphtheria, scarlet fever, and measles, as to smallpox and yellow fever.

Scarlet fever—scarlatina—as you doubtless know, is a highly contagious malady, which may be contracted at any age by those not protected by a previous attack, but is principally a disease of the developing period of life—youth—from infancy to 20 or 30 years. It is a disease, even when skillfully treated, which often leaves in its trail impairment of hearing, diminished eyesight, chronic sore throat, or kidney affection. Therefore, no one, specially a child, should be exposed under the fallacious idea, which is criminal, that children should have this disease before advancing to manhood or womanhood.

Anyone who would intentionally or needlessly expose another to the poison of scarlet fever, or any of the more highly contagious epidemic diseases, should be prosecuted by the law.

When scarlet fever is reported or suspected in a community, every sore throat accompanied by fever, and subsequently a rash, should be looked upon with uneasiness, and should be isolated from the well until the judgment of a physician is invoked.

Moderately severe cases generally present premonitory symptoms of sore-throat, high fever—from 103 to 105° F.—from twenty-four to thirty-six hours, and perhaps three days, when a bright red rash appears all over the body, accompanied with itching. The tongue has red papillæ (which are plainly seen), with red tip, and which gives it the appearance of a strawberry. A strawberry tongue, therefore, with the other symptoms mentioned, and with albuminous urine, is strongly indicative of scarlet fever. From ten days to two weeks, sometimes longer or shorter, according to individual cases, the rash fades and disappears, when the desquamation period begins. This is an effort of nature to cast off the dead epidermis—scarf skin—of the body. Scarlet fever is a necrobiotic disease, destructive to tissues principally glandular. It is at this stage of sickness that ear trouble is manifested, eye-sight impaired, or kidneys become acutely inflamed. And it is also at this stage that the contagious principle is most acute and readily communicable.

No adult or child sick from scarlet fever should be given liberty or allowed communication with the public generally, until the desquamation period is entirely and completely finished. Parents in their impatience and haste to be relieved from restrictive regulations, too often declare their child or children well who have lately been sick from scarlet fever, before they *are well*, and before this “scarf skin” shedding period is through with. Thus, in a few days or weeks, other cases are reported in the same neighborhood among children who have been visiting, or playing elsewhere, with the scarlet fever convalescents.

In addition to insisting upon and maintaining a proper isolation of the sick with their nurses, if the municipal or town authorities will require imperatively that a scarlet fever case shall not be released from restrictive regulations until the “shedding” stage is completely over, and will then see that the room, rooms, or entire premises, if deemed advisable, shall be *perfectly* disinfected, I think that you will have no difficulty in preventing scarlet fever from spreading beyond the initial cases.

Inauguration of national quarantine functions on the coast of Maine.

On December 5, 1901, at the request of the State board of health of Maine, a quarantine station was established at Eastport under the charge of Dr. E. M. Small, acting assistant surgeon, U. S. Marine-Hospital Service.

At the request of the State board of health of Maine, and under the provisions of the act of Congress, approved February 15, 1893, the U. S. Marine-Hospital Service assumed control of quarantine at Portland, Me., and on December 27, 1901, Surg. P. C. Kalloch, U. S. Marine-Hospital Service, was detailed by authority of the President as quarantine officer at that port, arriving there January 9, 1902.
